Aircraft Lateral Stability Analysis - PvdA
for longitudinal stability analysis, the sideslip angle plays important role for lateral & directional stability analysis. •
When an aircraft with good stability yaws, it generates rolling and yawing moments that tend to return back to equilibrium. These are called, positive lateral (rolling) and directional (yawing) stability, respectively.

By lateral stability we are referring to the stability of the aircraft when rolling one wing down/one wing up, and vice versa. As an aircraft rolls and the wings are no longer perpendicular to the direction of

MODERN METHODS OF AIRCRAFT STABILITY AND CONTROL ANALYSIS

Lateral Stability Derivatives • A key to understanding the lateral dynamics is roll-yaw coupling. • L_p rolling moment due to roll rate: – Roll rate p causes right to move wing down, left wing to move up
Vertical velocity distribution over the wing
 $W = py$ – Leads to a spanwise change in the AOA: $\alpha(y) = py/U_0$

The linearized equations of motion of a rigid aircraft can be decoupled into longitudinal dynamics which involve the motions in the plane of symmetry of the aircraft and lateral-directional dynamics which consist of the out of plane of symmetry motions.

Lateral Directional Approximations to Aircraft

Lateral stability is roll stability: the tendency of the aircraft to reduce its rolling and return to an upright position unless continually maintained in position by e.g. the ailerons. (This is usually only partial .)

A mathematical analysis of the longitudinal static stability of a complete aircraft (including horizontal stabilizer) yields the position of center of gravity at which stability is neutral. This position is called the neutral point. (The larger the area of the horizontal stabilizer, and the greater the moment arm of the horizontal stabilizer about the aerodynamic center, the further aft is the neutral point.)

Longitudinal static stability - Wikipedia
Lateral stability is a function of the yawing and rolling moments, the lateral force and their associated cross coupling. The stability of the airplane from these forces and moments must be determined by a dynamic analysis as the motion is time dependent.

two topics are divided into longitudinal, lateral and directional modes. Another important element in stability analysis is the static margin for free and fixed stick. This margin is a crucial parameter that determines certain behaviors related to aircraft's maneuverability. During ground manoeuvres a loss of lateral stability due to the saturation of the mainlanding gear tyres can cause the aircraft to enter a skid or a spin. The lateral stability is governed not only by aspects of the gear design, such as its geometry and tyre characteristics, but also by operational parameters, for example, the weather and taxiway condition.
