Electric Power Transmission And Distribution

Electric power distribution is the final stage in the delivery of electric power; it carries electricity from the transmission system to individual consumers. Distribution substations connect to the transmission system and lower the transmission voltage to medium voltage ranging between 2 kV and 35 kV with the use of transformers. Primary distribution lines carry this medium voltage power to distribution transformers located near the customer's premises. Distribution transformers again lower the

Electric power distribution - Wikipedia

For other uses, see Electric transmission (disambiguation). Electric power transmission is the bulk movement of electrical energy from a generating site, such as a power plant, to an electrical substation. The interconnected lines which facilitate this movement are known as a transmission network. This is distinct from the local wiring between high-voltage substations and customers, which is typically referred to as electric power distribution.

Transmission Line- Normally carries electricity at voltages of 69 kV or greater and is used to transmit electric power over relatively long distances, usually from a central generating station to main substations. Distribution Line-Normally considered to be a line that carries electricity at lower voltages of 12kV to 44kV and is used to distribute power drawn from high-voltage transmission systems to end-use customers.

An Introduction to Electric Power Transmission Presentation

Power transmission is defined as the movement of electrical energy from a generating site like power plant. Power transmission and distribution conductors are used for all transmission and distribution purposes. They are classified into various types including AAC (All Aluminum Conductor), and ASCR (Aluminum conductor, steel reinforced).
