numerical parameter λ is introduced in front of the integral for reasons that will become apparent in due course. We shall mainly deal with equations of the second kind. Series solutions One fairly obvious thing to try for the equations of the second kind is to make an expansion in λ and hope that, at least for small enough values, this might converge. To illustrate the method let us begin with a simple Volterra equation, $\phi(x) = x + \lambda \int_0^x \phi(s) ds$. For small λ , $\phi \approx x$.

1 Introduction The integral equation problem is to find the solution to: $h(x)f(x) = g(x) + \int_a^b k(x;y)f(y)dy$: (1) We are given functions $h(x)$, $g(x)$, $k(x;y)$, and wish to determine $f(x)$. The quantity is a parameter, which may be complex in general. The bivariate function $k(x;y)$ is called the kernel of the integral equation.

1 Introduction

The most basic type of integral equation is called a Fredholm equation of the first type, $\{\displaystyle f(x) = \int_a^b K(x,t)\varphi(t)dt\}$. The notation follows Arfken. Here φ is an unknown function, f is a known function, and K is another known function of two variables, often called the kernel function.

As the general form of Fredholm Integral Equation is $g(x) y(x) = f(x) + \lambda \int_a^b K(x, t) y(t) dt$, there may be following other types of it according to the values of g and f : 1. Fredholm Integral Equation of First Kind —when — $g(x) = 0$ $f(x) + \lambda \int_a^b K(x, t) y(t) dt = 0$ 2.

There is a close correspondence between linear integral equations, which specify linear, integral relations among functions in an infinite-dimensional function space, and plain old linear equations, which specify analogous relations among vectors in a finite-dimensional vector space.
